ABSTRACT
Recent studies have demonstrated that dysregulation of macroautophagy/autophagy may play a central role in the pathogenesis of neurodegenerative disorders, and the induction of autophagy protects against the toxic insults of aggregate-prone proteins by enhancing their clearance. Thus, autophagy has become a promising therapeutic target against neurodegenerative diseases. In this study, quantitative phosphoproteomic profiling together with a computational analysis was performed to delineate the phosphorylation signaling networks regulated by 2 natural neuroprotective autophagy enhancers, corynoxine (Cory) and corynoxine B (Cory B). To identify key regulators, namely, protein kinases, we developed a novel network-based algorithm of in silico Kinome Activity Profiling (iKAP) to computationally infer potentially important protein kinases from phosphorylation networks. Using this algorithm, we observed that Cory or Cory B potentially regulated several kinases. We predicted and validated that Cory, but not Cory B, downregulated a well-documented autophagy kinase, RPS6KB1/p70S6K (ribosomal protein S6 kinase, polypeptide 1). We also discovered 2 kinases, MAP2K2/MEK2 (mitogen-activated protein kinase kinase 2) and PLK1 (polo-like kinase 1), to be potentially upregulated by Cory, whereas the siRNA-mediated knockdown of Map2k2 and Plk1 significantly inhibited Cory-induced autophagy. Furthermore, Cory promoted the clearance of Alzheimer disease-associated APP (amyloid β [A4] precursor protein) and Parkinson disease-associated SNCA/α-synuclein (synuclein, α) by enhancing autophagy, and these effects were dramatically diminished by the inhibition of the kinase activities of MAP2K2 and PLK1. As a whole, our study not only developed a powerful method for the identification of important regulators from the phosphoproteomic data but also identified the important role of MAP2K2 and PLK1 in neuronal autophagy.

Introduction
Autophagy is a cellular pathway for the degradation of long-lived proteins, aggregates and damaged organelles via lysosomes. In neurodegenerative diseases, proteins typically accumulate in the central nervous system as the disease progresses, and defective autophagy has been observed in the brains of patients with neurodegenerative diseases and in related animal models. Defective autophagy in neurons causes neurodegenerative disease-like phenotypes in mice, whereas enhanced autophagy is found to be neuroprotective by promoting the clearance of disease-associated aggregates. Therefore, small-molecule autophagy enhancers have been suggested as potential drugs for the treatment of neurodegenerative diseases. Previously, we identified 2 neuroprotective autophagy enhancers, corynoxine (Cory) and corynoxine B (Cory B), from the Chinese herbal medicine Uncaria rhynchophylla (Gouteng). Although the structures of Cory and Cory B differ only in the stereochemistry of the spiro carbon, the manners in which they induce autophagy are quite different, and the reasons for this are still unclear.

Protein phosphorylation is one of the most important post-translational modifications in living cells and is involved in the regulation of a large number of biological processes, such as cell cycle, signal transduction, differentiation, proliferation, metabolism, and autophagy. Advances in proteomic technology with a rapid development of liquid chromatography-tandem mass spectrometry (LC/MS-MS) have provided a great opportunity to study phosphorylation events in detail. Recently, several phosphoproteomic studies were performed to characterize the landscape of the phosphorylation dynamics in autophagy. For example, Yeh et al. adopted nanoLC-MS/MS to identify 15 potential phosphorylation sites (p-sites) on Atg1 in the yeast Saccharomyces cerevisiae and confirmed that phosphorylation of S34 inhibits both Atg1 kinase activity and autophagy. Using the stable isotope labeling by amino acids in cell culture (SILAC) labeling technique, Harder et al. performed a
quantitative phosphoproteomic analysis of ammonia- or rapamycin-induced autophagy and observed that up to 328 p-sites were only significantly up- or downregulated by ammonia, in an MTOR (mechanistic target of rapamycin [serine/threonine kinase])-independent manner. In addition, Rigbolt et al. quantified 6,801 p-sites in 2,155 proteins from MCF-7 human breast cancer cells treated with rapamycin or subjected to starvation and discovered several MAP1LC3-interacting proteins that exhibit distinct phosphorylation dynamics upon starvation or rapamycin treatment. Although both nonquantitative and quantitative proteomic techniques have been widely used, the identification of key upstream regulators, namely, protein kinases from the phosphoproteomic data, is still difficult.

In this study, we systematically quantified the phosphoproteome in mouse neuroblastoma cell line N2a treated with Cory and Cory B. To identify the potential kinases that were significantly regulated by Cory or Cory B, we developed a novel algorithm of in silico Kinome Activity Profiling (iKAP) to computationally infer the kinase activities from the phosphoproteomic data. With the help of iKAP, 3 kinases, including Rps6kb1, Map2k2 and Plk1, were predicted to be specifically up- or downregulated by Cory. We found that Cory, but not Cory B, increases the phosphorylation level and kinase activity of Map2k2 and Plk1, whereas the siRNA-mediated knockdown of Map2k2 and Plk1 inhibited Cory-induced autophagy, although Plk1 depletion also affected Cory B-induced autophagy. Moreover, the inhibition of Map2k2 and Plk1 diminished the clearance of Alzheimer disease-associated APP/β-amyloid precursor protein, and Parkinson disease-associated SncA/α-synuclein by Cory-induced autophagy. In this regard, our studies demonstrated that both Map2k2 and Plk1 are essential in the regulation of neuronal autophagy.

**Results**

**A large-scale quantification of the phosphoproteome in compound-induced autophagy**

Using SILAC coupled to LC-MS/MS, we systematically profiled the quantitative phosphoproteome in N2a cells treated with 15 μM Cory or Cory B for 3 h, both of which could efficiently induce neuronal autophagy (Fig. 1, Fig. S1). In total, we identified 5,328 unique phosphopeptides (Table S1) and observed that a large proportion of the phosphopeptides (3,943; 74.0%) were matched with more than one spectral count, whereas the average spectral counts for each phosphopeptide were calculated as 5.5 (Fig. 2A). By mapping the phosphopeptides to their corresponding protein sequences, we comprehensively quantified 2,233 phosphoproteins with 5,413 unique p-sites, including 4,749 p-Ser (~87.7%), 643 p-Thr (~11.9%), and 21 p-Tyr (~0.4%) sites (Fig. 2B, Table S2). There were 2,070 proteins (38.2%) identified with ≤5 p-sites and only a few proteins (58 proteins, 1.1%) contained ≥10 p-sites (Fig. 2C). To assess the reliability of the phosphoproteomic identification, we retrieved 132,159 known mouse p-sites from 8 public databases, including PhosphoELM, dbPTM, PHOSIDA, SysPTM, PTMfunc, PhosphoSitePlus, dbPAT and UniProt. In comparison, we found that up to 5,150 (~95.1%) p-sites quantified in this study were annotated and included in at least one phosphorylation database (Fig. 2D). The high overlapping rate suggested that most of our identifications were bona fide p-sites with high confidence.

With the comparison of the modification levels of p-sites in the Cory and Cory B groups, we observed that the Cory:Cory B ratio of most p-sites was mainly centered at 1.0 with a relatively low variance, and the results demonstrated that only a small proportion of p-sites were potentially regulated upon the Cory or Cory B treatment, in a direct or indirect manner (Fig. 2E). Using a 2-fold change threshold, we found that the phosphorylation levels of the 126 and 103 p-sites were dramatically increased and decreased by Cory, respectively (Fig. 2F).
Additionally, there were 91 and 98 p-sites significantly up- and downregulated by Cory B, respectively (Fig. 2F). In a recent study, we developed an integrative database known as The Autophagy, Necrosis, ApopTosis OrchestratorS (THANATOS, http://thanatos.biocuckoo.org), which contains both known and highly likely proteins involved in regulating autophagy and cell death pathways, based on experimental evidence or an orthologous search. We mapped 196 and 168 proteins with at least one 2-fold changed p-site in the Cory and Cory B groups respectively, to 763 mouse proteins associated with autophagy in THANATOS and found that 19 phosphoproteins had been annotated as autophagy regulators in the database (Fig. 2G, Table S3). Whether these proteins are implicated in Cory- or Cory B-induced autophagy remains to be further dissected.

In addition, we performed enrichment analyses of biological processes based on Gene Ontology (GO) annotations for the phosphoproteins in the Cory and Cory B groups using the gene set enrichment analysis (GSEA) approach, which took the quantification information into account. Obviously, different GO terms were significantly associated with the 2 drug treatments (Fig. 2H). For example, DSB repair via homologous recombination (GO:0000724) and axon guidance (GO:0007411) were highly enriched in Cory-treated cells, while RNA-related processes such as mRNA processing (GO:0006397) and RNA splicing (GO:0006830) were significantly over-represented in the Cory B treatment group (Fig. 2H). Thus, our analyses indicated that there were potentially distinct mechanisms for the regulation of neuronal autophagy induced by the 2 compounds. Although thousands of p-sites have been quantified, the regulatory kinases responsible for modifying these p-sites were still elusive. Additionally, it was not known whether some of these kinases were involved in regulating neuronal autophagy.

A novel computational method for inferring protein kinase activities from a weighted kinase-site phosphorylation network

Although the Cory and Cory B treatment groups could not be easily distinguished directly from the p-sites, we asked whether there were any particular protein kinases that played distinct roles in these 2 groups. To address this question, we developed a novel network-based method, iKAP, to computationally infer significant changes in the kinase activity from the phosphoproteomic data. The basic idea was derived from the working concept that the more important kinases preferentially induce
more significant changes in the phosphorylation network level rather than at a single p-site. For example, if the activity of a kinase is increased, it will produce a more positive regulation of the phosphorylation network and vice versa. In this study, we used the quantification ratio, an indicator of phosphorylation changes at the phosphopeptide level, as the weight information, which explicitly reflected the differential regulation of protein kinases on substrates in the phosphorylation network.

Here, to obtain upstream kinases with high confidence and to construct the phosphorylation network, a prediction of site-specific kinase-substrate relationships (ssKSRs) and the integration of protein-protein interactions between kinases and substrates was performed for the phosphoproteomic data (Fig. 3A). Simply, we hypothesized that the change to the phosphopeptide level was uniformly derived from each of its kinases and mapped the ratio information to each kinase-site association. Then, we constructed a weighted kinase-site phosphorylation network (WKSPN) containing 360 protein kinases, 1,524 substrate sites and 21,065 ssKSRs (Fig. 3B).

To investigate the changes in kinase activities induced by the drug treatment, we first extracted 360 single-kinase networks and then separated the network into 2 subnetworks based on the ratio change for each kinase. In our study, the network containing p-sites with ratios > 1 was considered as the upregulated network, while the network containing p-sites with ratios < 1 was considered as the downregulated network (Fig. 3C). To statistically test which network was preferentially regulated by the kinase, the Yate’s Chi-square test was performed for a network comparison (Fig. 3D). At a significance level of p-value < 0.05, the number of protein kinases that were significantly up- and downregulated by Cory was 38 and 43, respectively. Meanwhile, the number of protein kinases that were significantly up- and downregulated by Cory B was 22 and 35, respectively.

**Identification of potentially important protein kinases in neuronal autophagy**

To further investigate protein kinases that were potentially involved in Cory- or Cory B-induced autophagy, all kinases were mapped to THANATOS, which contained 118 mouse protein kinases annotated as autophagy regulators (Fig. 4A, B, Table S4). Through direct mapping, 7 up- and 12 downregulated kinases induced by Cory (Fig. 4A, C) and 2 up- and 11 downregulated kinases induced by Cory B were detected as autophagy regulators, respectively (Fig. 4B, D). From the results, we observed that the kinase activity of CDK1, a cyclin-dependent kinase, was highly upregulated by both Cory and Cory B (Fig. 4C, D), suggesting that cell cycle events might be commonly regulated in the neuroprotective autophagy process. Additionally, PRKAA2, a component of the AMP-activated protein kinase (AMPK) that inhibits the phosphatidylinositol 3-kinase complex that is not involved in autophagy by phosphorylating PIK3C3, was predicted to be downregulated in both the Cory and Cory B groups (Fig. 4C, D). In addition, we observed that AKT family members, including AKT1, AKT2 and AKT3, were significantly downregulated by both compounds during autophagy. This result was also consistent with a previous study that AKT1 led to the inhibition of autophagy by downregulating the expression of UVRAG (UV radiation resistance associated gene). Taken together, our results highlighted common mechanisms that exist in compound-induced neuronal autophagy and provided potentially important targets for the therapy of neurodegenerative diseases.
Interestingly, we observed that there were several kinases potentially regulated by only Cory or Cory B. For example, RPS6KB1 (ribosomal protein S6 kinase, polypeptide 1), a serine/threonine protein kinase, was significantly downregulated by Cory, but not by Cory B. Previously, we found that Cory, but not Cory B, induced autophagy potentially through the MTOR pathway by reducing the phosphorylation level of RPS6KB1.

With an immunoblotting analysis, we simultaneously detected the phosphorylation levels of RPS6KB1 at T389, a p-site positively correlated with RPS6KB1 kinase activity, with the treatment of Cory and Cory B. Our results confirmed that Cory, but not Cory B, significantly decreased the phosphorylation level and kinase activity of RPS6KB1 (Fig. 4E, F).

Next, we aimed to discover new protein kinases that participate in the regulation of neuronal autophagy. We mainly focused on protein kinases with significantly upregulated activities since these kinases may be directly or indirectly activated upon Cory or Cory B treatment. In our results, the kinase activities of MAP2K2 and PLK1 were predicted to be exclusively upregulated in Cory-induced autophagy. As a member of the MAPKK or MAP2K family, MAP2K2 was reported to be associated with tumourigenesis and involved in the well-known RAS-RAF-MAP2K/MEK-MAPK/ERK pathway, which positively regulates autophagy in response to starvation and curcumin treatment in human cancer. PLK1, a key protein kinase that functions throughout the M phase of the cell cycle, is often overexpressed in human tumors. The inhibition of PLK1 kinase activity leads to apoptosis, necroptosis, and attenuated autophagy in cancer. Although both kinases are involved in the autophagy of human cancers, it is unknown whether MAP2K2 and PLK1 participate in the regulation of neuronal autophagy.

To validate the upregulated change of MAP2K2, an immunoblotting analysis was performed to measure the phosphorylation level of MAP2K2 S222, which is phosphorylated by RAF or MAP3Ks and positively correlated with MAP2K2 kinase activity. Indeed, a significant upregulation in phospho-MAP2K2 was found in Cory-treated cells, while a stable level was observed in the Cory B-treated group, suggesting that Cory upregulated the activity of MAP2K2 (Fig. 4G, H). Meanwhile, we measured the phosphorylation level of PLK1 at T210, which is phosphorylated by AURKA/Aurora-A and positively correlates with PLK1 kinase activity. Similar to MAP2K2, Cory but not Cory B increased the phospho-PLK1 level at T210 (Fig. 4I, J). These experiments are consistent with the iKAP results and

Figure 4. The phosphoproteome-based identification of protein kinases potentially involved in neuronal autophagy. We used the iKAP algorithm for the prediction of differentially regulated kinases (p-value < 0.05) and adopted mouse proteins annotated in THANATOS to filter potentially false positive hits for the (A) Cory and (B) Cory B groups. (C) The list of kinases differentially regulated by Cory. (D) The differentially regulated kinases induced by Cory B. (E) The total (t-) protein and phosphorylation (p-) levels of RPS6KB1 were measured to probe the RPS6KB1 activity dynamics upon Cory or Cory B treatment. (F) Cory but not Cory B decreases the phosphorylation level and the kinase activity of RPS6KB1 (**p < 0.001, Cory vs. Ctrl). (G) The total protein and phosphorylation levels of MAP2K2 were measured. (H) Cory increases the phosphorylation level and kinase activity of MAP2K2 (p < 0.05; ns, not significant). (I) The total protein and phosphorylation dynamics of PLK1. (J) Cory increases the PLK1 activity (**p < 0.01, Cory vs. Ctrl).
suggest that both kinases might play potential roles in Cory-induced autophagy.

**MAP2K2 and PLK1 are required for autophagy-associated clearance of pathological proteins in neurodegenerative diseases**

To confirm whether MAP2K2 and PLK1 are involved in neuronal autophagy, we performed siRNA experiments to knock down Map2k2 or Plk1 (Fig. S2A, S2B). From the results, we found that both Cory and Cory B induced an increase in MAP1LC3B/LC3B (microtubule-associated protein 1 light chain 3 β)-II (Fig. 5A, B, C). For Cory, the increase in LC3B-II was diminished by Map2k2 silencing, but dramatically enhanced by the depletion of Plk1 (Fig. 5A, B). In contrast, the LC3B-II increased by Cory B was not influenced by Map2k2 knockdown but considerably enhanced by Plk1 silencing (Fig. 5B, C). Additionally, both Cory and Cory B significantly reduced SQSTM1/p62, whereas Map2k2 deprivation only blocked the effect in Cory- but not Cory B-treated cells (Fig. 5D, E, F). Thus, it could be proposed that MAP2K2 is mainly involved in Cory- but not Cory B-induced autophagy. However, Plk1 silencing inhibited the effect caused by both Cory and Cory B, and the results suggested that both compounds potentially regulate PLK1.

To evaluate whether MAP2K2 and PLK1 are essential for ensuring the neuroprotective effects generated by Cory, we first inhibited the kinase activity of MAP2K2 or PLK1 using kinase inhibitors U0126 or BI2356, respectively (Fig. 6A). Immunoblotting analyses revealed that the Cory-mediated SQSTM1 decrease was diminished by the inhibition of MAP2K2 or PLK1, whereas the effect of the LC3B-II increase by Cory was blocked by MAP2K2 inhibition but greatly enhanced by BI2356 (Fig. 6B, C, D). The results were consistent with the observations from the siRNA experiments and confirmed that both kinases were involved in Cory-induced autophagy. Previously, we found that Cory promotes the clearance of wild-type and mutant SNCA by inducing autophagy. In this study, full-length APP (FI-APP), which is associated with the progress of Alzheimer disease, was also found to be degraded by Cory in N2S cells, which stably express a human Swedish mutant, APP695 (Fig. 6E, F). From the results, we found that the Cory-mediated clearance of FI-APP was greatly diminished by the inhibition of MAP2K2 and PLK1 (Fig. 6E, F). In addition, the Cory-mediated clearance of the mutant SNCAA53T, a molecular marker associated with Parkinson disease, was also blocked by the inhibition of the 2 kinases (Fig. 6G, H). In this regard, the inhibition of either MAP2K2 or PLK1 attenuated Cory-induced autophagy and disrupted the clearance of the overexpressed neurodegenerative disease-associated proteins. The results demonstrated that both MAP2K2 and PLK1 play critical roles in neuronal autophagy.

**Discussion**

Abnormal accumulation of protein aggregates and defective autophagy are hallmarks of neurodegenerative diseases. It has been demonstrated that small-molecule autophagy inducers can enhance neuronal autophagy, prompt the clearance of dysfunctional cellular components or proteins, and be used as potent drugs for the treatment of Alzheimer and Parkinson diseases. However, the molecular mechanisms of neuronal autophagy are far from being fully understood, and how these autophagy enhancers generate neuroprotective effects in the context of neurodegenerative diseases remains to be delineated. As one of the mostly characterized PTMs, phosphorylation is involved in almost all cellular processes and plays a critical role in the regulation of autophagy. Recently, advances in
the development of phosphoproteomic techniques have enabled the identification and quantification of thousands of p-sites in a single run, and several autophagy-responsive phosphoproteomes have been characterized. For example, Harder et al. quantified 5,901 p-sites in 1,931 proteins from MCF-7 cells treated with ammonia or rapamycin, which is a widely used MTOR inhibitor for the induction of autophagy. They performed 2 technical replicates, and up to 80.5% of p-sites were simultaneously detected in both replicates. Additionally, Rigbolt et al. performed 2 biologic replicates and comprehensively quantified 6,801 p-sites in starvation- or rapamycin-induced autophagy. The median relative standard deviation of the site quantifications between the 2 replicates was calculated as 11.6%, and such a small deviation indicated that the reproducibility of the phosphoproteomic quantifications was highly promising. Later, Alayev et al. performed 2 biological replicates and quantified 3,042 p-sites of 1,289 proteins from serum-deprived MCF-7 cells with an acute resveratrol treatment. They not only observed that a similar number of phosphopeptides was detected in each replicate but also found that the distribution of phosphopeptide quantifications was also highly similar between the 2 biological replicates. Taken together, the results from both the technical and biologic replicates supported a satisfying reproducibility of quantitative phosphoproteomic profiling.

To find potentially important kinases involved in regulating neuronal autophagy, we quantified a phosphoproteome from N2a cells treated with 2 natural isomer compounds: Cory and Cory B. By developing a network-based method, iKAP, we comprehensively predicted 19 and 13 protein kinases to be significantly up- or downregulated by Cory and Cory B, respectively. We experimentally validated the activities of 3 differentially regulated kinases including RPS6KB1, MAP2K2 and PLK1, and the results supported the accuracy of the iKAP predictions. We also compared iKAP to GSEA, a widely used algorithm for analyzing gene expression profiles. We performed the GSEA analysis using the p-site ratio information (p-value < 0.05) and filtered the results using the THANATOS database. By comparison, we observed that GSEA only identified 13 protein kinases to be significantly up- or downregulated by Cory and Cory B, and 4 of these kinases were covered by iKAP (Fig. S3). In the Cory-treated group, GSEA correctly

Figure 6. The clearance of overexpressed APP and SNCA by Cory was greatly diminished through the inhibition of MAP2K2 or PLK1. (A) U0126 inhibits the phosphorylation and kinase activity of MAP2K2. (B) BI2356 reduces the PLK1 activity. (C) The changes in LC3B-II and SQSTM1 treated with Cory, after the inhibition of MAP2K2 or PLK1. (D) Quantifications of the SQSTM1:ACTB ratio. (E) Quantifications of the LC3B-II:ACTB ratio. (F) The clearance of FI-APP by Cory, after the inhibition of MAP2K2 or PLK1. (G) Quantifications of the FI-APP:ACTB ratio. predicted MAP2K2 as a differentially regulated kinase, but missed RP56KB1 and PLK1 (Fig. S3). Thus, our results demonstrated that the GSEA prediction was quite stringent, and too many potentially positive hits were neglected.

To gain more molecular insights into the potential roles of MAP2K2 and PLK1 in neuronal autophagy, we further predicted 35 and 140 p-sites in 34 and 64 substrates specifically modified by MAP2K2 and PLK1 from the phosphoproteomic data, respectively (Table S5). Then, we mapped these p-sites to the THANATOS database and found that 10 and 14 MAP2K2- and PLK1-specific substrates were annotated to be associated with mouse autophagy (Table S5). From 14 annotated PLK1-specific substrates, we did not find any p-sites exhibiting a ≥2-fold change between the Cory and Cory B treatments (Table S5). Thus, the PLK1 regulation in neuronal autophagy is complicated, and its major substrates involved in autophagy are difficult to identify. However, we observed several annotated MAP2K2-specific substrates containing at least 1 differentially regulated p-site between the Cory and Cory B treatments (Table S5). For example, it was reported that the phosphorylation of human RB1 (RB transcriptional corepressor 1) at S807/S811 (S800/S804 in mouse) inhibits apoptosis by promoting its interaction with the pro-apoptotic protein BAX, whereas RB1 deprivation blocks the autophagic flux. In the results, we found a single p-site for mouse RB1 at S804 that was upregulated by Cory (2.51-fold) but downregulated by Cory B (0.69-fold) relative to the control, with a Cory:Cory B ratio of 3.62. Because MAP2K2 was predicted and validated to be specifically activated by Cory but not Cory B, the significantly higher phosphorylation level of RB1 S804 potentially inhibits apoptosis and promotes autophagic flux upon activation of MAP2K2 and might partially explain the different mechanisms of the 2 compounds. Additionally, we found that the T497 of PRKCA/PKCα and S348 of the histone acetyltransferase KAT8 were differentially phosphorylated with Cory: Cory B ratios of 2.88 and 2.02, respectively. Both proteins were reported to negatively regulate autophagy. A determination of whether the phosphorylation inhibits the activity of the 2 proteins to promote autophagy will require a further investigation.

Starvation is a classical treatment to induce autophagy. To justify whether MAP2K2 and PLK1 would be activated by starvation, the time-course changes of the protein and phosphorylation levels of MAP2K2 and PLK1 were analyzed after the starvation treatment (Fig. S4). Interestingly, we found that the phosphorylation levels of MAP2K2 and PLK1 were only significantly upregulated at the early stages of starvation-induced autophagy within 30 min, at the time that LC3B-II levels were not increased at all (Fig. S4). After one h, both MAP2K2 and PLK1 were no longer activated. In our study, we first observed that a higher concentration (25 μM) of Cory induced higher phosphorylation levels of MAP2K2 and PLK1 at 6 h (Fig. S5A, S5B), and a time-series analysis of the 2 kinases was performed by adopting this higher dose. From the results, we found that the phosphorylation levels of MAP2K2 and PLK1 were significantly increased after a 1-h treatment with Cory but not Cory B. (Fig. S5C-F). In this regard, although MAP2K2 and PLK1 were potentially involved in starvation-induced autophagy, our analyses suggested that both kinases might play more specific and important roles in compound-induced autophagy. From the results, Cory induces an increase in LC3B-II and a decrease of SQSTM1 to promote autophagic flux, whereas the inhibition or depletion of MAP2K2 greatly diminishes both effects (Fig. 5, 6).

Although the depletion of PLK1 enhances the effect of increased LC3B-II by Cory, PLK1 silencing blocks the Cory-mediated decrease of SQSTM1 (Fig. 5, 6). Thus, MAP2K2 might be essential for the induction of autophagy, whereas PLK1 plays a potential role in the maturation of the autophagosome (Fig. 7). In addition, we determined cell death and viability by measuring the relative release of LDH (lactate dehydrogenase) from N2a cells treated with different concentrations of Cory and Cory B for 24 h; the doses for either the phosphoproteomic quantification (15 μM) or further validations (25 μM) did not influence cell viability (Fig. S6A, S6B).

Altogether, this study provides a novel network-based approach, iKAP, to computationally infer differently regulated protein kinase activities using quantitative phosphoproteomic data. Our validation results supported the accuracy and efficiency of this new method. Using iKAP, we predicted several protein kinases to be differentially up- or downregulated by 2 isomers, Cory and Cory B, that induced neuronal autophagy. The analysis provides new evidence for the important roles of MAP2K2 and PLK1 in the autophagy of neurodegenerative disease, which will be helpful for further experimental and clinical studies. We anticipate that iKAP can also be extended to the analysis of the phosphoproteomes of other diseases or treatments.

Materials and methods

Reagents and antibodies

H2O was purchased from Thermo (10977023); ACN (acetonitrile; A998–1) and fa (ethyl alcohol; A995–4) was purchased from Fisher Chemical; formic acid (FA; 5.43804) was purchased from Fluka; DMEM medium (11965118) and fetal bovine serum (FBS; 16000044) were purchased from Invitrogen; SILAC™ Protein
Identification and Quantitation Media Kit was purchased from Thermo (SP10001); Sequencing Grade Modified Trypsin was purchased from Promega (V5280); trifluoroacetic acid (TFA; 574732); iodoacetamide (A3221) and dithiothreitol (43817) were purchased from Sigma; 2-D Quant kit was purchased from GE Healthcare (80–6483–56); IMAC beads was purchased from Dalian Institute of Chemical Physics. Corynoxine and Corynoxine B were purchased from Aktin Chemicals (APC-461, APC-459); 3-methyladine (3-MA; M9281), doxycycline (Dox, D9891) and chloroquine (CQ, C6628) were purchased from Sigma-Aldrich. BI2356 (PLK1 inhibitor) for 2 h and then co-treated with 25 \( \mu \)M Cory, 25 \( \mu \)M Cory B or 0.1% (v/v) dimethyl sulfoxide (DMSO) for another 24 h. For the kinase inhibitions on the clearance of FI-APP, N2a cells were pretreated with 12.5 \( \mu \)M Cory, 25 \( \mu \)M Cory B or 0.1% (v/v) dimethyl sulfoxide (DMSO) for another 6 h. To analyze the effects of the kinase inhibitions on the clearance of FI-APP, N2a cells were pretreated with siMap2k2, siPlk1 or non-targeted siRNAs for 48 h and then treated with 25 \( \mu \)M Cory, 25 \( \mu \)M Cory B or 0.1% (v/v) dimethyl sulfoxide (DMSO) for another 6 h. To analyze the effects of the kinase inhibitors on the clearance of FI-APP, N2a cells were pretreated with 12.5 \( \mu \)M Cory or 0.1% (v/v) DMSO for another 24 h. For the analysis of the clearance of mutant SNCA, inducible PC12/A53T-SNCA cells were first treated with 1 \( \mu \)g/ml doxycycline (Dox) for 24 h to induce the expression of mutant SNCA (A53T). Then, the cells were pretreated with 12.5 \( \mu \)M Cory or 0.1% (v/v) DMSO for another 24 h. To perform the LDH assay, we treated N2a cells with different concentrations of Cory, Cory B or 0.1% (v/v) DMSO (control) for 24 h, whereas the supernatant was collected and analyzed using the LDH kit.

**Immunoblotting analysis**

Cells were lysed with RIPA lysis buffer (Thermo, 89900) with protease inhibitor (Merck, 539137). The boiled samples (each containing 10–20 \( \mu \)g of protein) were subjected to SDS-PAGE on a 10–15% acrylamide gel and transferred to PVDF membranes (GE Healthcare, RPN303F). The membranes were blocked for 1 h in TBST (CST, 9997) containing 5% nonfat milk and then probed with the appropriate primary and secondary antibodies. The desired bands were visualized using the ECL kit (Pierce, 32106). The band density was quantified using the ImageJ program and normalized to the band density of the control group. As described previously, one-way ANOVA with the Newman-Keuls test was performed to analyze the data. At least 3 replicates of independent experiments were performed for each immunoblotting assay, and the data were presented as the mean ± SEM of multiple (≥3) independent experiments.

**Isolation of peptides and determination of labeling efficiency**

N2a cells were grown in light, middle or heavy medium for 3 and 6 d. The labeling efficiency was determined according to a previously published protocol with small modifications. Cell pellets were first incubated with 100 \( \mu \)l of 0.1% TFA for 5 min at 4°C, incubated in a sonication bath for another 5 min and centrifuged for 10 min at 12000 g at 4°C. The supernatant was concentrated by speed vac and purified using \( \mu \)-C18 ZipTips (Millipore, ZTC8M906). The eluate was added to the Nano-LC/Ion Trap MS (Ultimate 3000, Dionex; amaZon ETD, BRUKER) mass spectrometer as described below. In the Mascot search engine, “none” enzyme was selected, and N-acetyl (protein) was chosen as the variable modification.

**Total protein extraction for phosphoproteomic profiling**

Cell pellets were lysed with lysis buffer (Thermo, 89900) supplemented with Phosphatase Inhibitor Cocktail (Merck, 524625) and Protease Inhibitor Cocktail (Merck, 539137) on ice using a high-intensity ultrasonic processor (Sientz) for 30 min. The supernatants were collected after centrifuging at 20,000 g for 10 min at 4°C. The protein concentration was determined with a 2-D Quant kit according to the manufacturer’s instructions.

**HPLC fractionation and phosphopeptide enrichment**

After digestion with trypsin, the sample was fractionated into fractions by high-pH reverse-phase HPLC using the Agilent 300 Extend C18 column (5 \( \mu \)m particles, 4.6 mm ID, 250 mm length). Briefly, peptides were first separated with a gradient of 2% to 60% acetonitrile in 10 mM ammonium bicarbonate pH 10 over 80 min into 80 fractions. Then, the peptides were combined into 12 fractions and dried by vacuum centrifugation. For phosphopeptide enrichment, fractionated peptide mixtures were first incubated with an IMAC microsphere suspension by vibration. The IMAC microspheres with enriched phosphopeptides were collected by centrifugation, and the supernatant was removed. To remove nonspecifically adsorbed peptides, the IMAC microspheres were washed with 50% ACN:6% TFA and 30% ACN:0.1% TFA, sequentially. To elute the enriched phosphopeptides from the IMAC microspheres, elution buffer containing 10% \( \text{NH}_4\text{OH} \) was added and the enriched phosphopeptides were eluted with vibration. The supernatant containing phosphopeptides was collected and lyophilized for the LC-MS/MS analysis.
**LC-MS/MS analysis**

Peptides were dissolved in solvent A (0.1% FA in 2% ACN), directly loaded onto a reversed-phase precolumn (Acclaim PepMap 100, Thermo Scientific). Peptide separation was performed using a reversed-phase analytical column (Acclaim PepMap RSLC, Thermo Scientific) with a linear gradient of 5-20% solvent B (0.1% FA in 98% ACN) for 50 min, 20–35% solvent B for 10 min, and 35–80% solvent B for 10 min at a constant flow rate of 300 nl/min on an EASY-nLC 1000 UPLC system. The resulting peptides were analyzed with a Q Exactive™ Plus hybrid quadrupole-Orbitrap mass spectrometer (Thermo Fisher Scientific).

The peptides were subjected to an NSI source followed by tandem mass spectrometry (MS/MS) in Q Exactive™ Plus (Thermo) coupled online to the UPLC. Intact peptides were detected in the Orbitrap at a resolution of 70,000. Peptides were selected for MS/MS using 28% NCE; ion fragments were detected in the Orbitrap at a resolution of 17,500. A data-dependent procedure that alternated between one MS scan followed by 10 MS/MS scans was applied for the top 10 precursor ions above a threshold ion count of 2E4 in the MS survey scan and a 5.0-s dynamic exclusion. The electrospray voltage applied was 2.0 kV. Automatic gain control (AGC) was used to prevent overfilling of the ion trap; 5E4 ions were accumulated for generation of MS/MS spectra. For MS scans, the m/z scan range was 350 to 1800.

**Database search**

The resulting MS/MS data were processed using MaxQuant with integrated Andromeda search engine (v.1.4.1.2). Tandem mass spectra were searched against Swiss-Prot mouse database concatenated with reverse decoy database. Trypsin/P was specified as cleavage enzyme allowing up to 2 missing cleavages, 4 modifications per peptide and 5 charges. Mass error was set to 10 ppm for precursor ions and 0.02 Da for fragment ions. Carbamidomethylation on Cys was specified as fixed modification and oxidation on Met, phosphorylation on Ser, Thr, Tyr and acetylation on protein N-termini were specified as variable modifications. False discovery rate thresholds for protein, peptide and modification site were specified at 1%. Minimum peptide length was set at 7. All the other parameters in MaxQuant were set to default values. The mass spectrometry proteomics data including the annotated mass spectra have been deposited to the ProteomeXchange Consortium via the PRIDE partner repository with the data set identifier PXD004891 (Reviewer account: reviewer61816@ebi.ac.uk; Password: 6kOmNOzP; Login: http://www.ebi.ac.uk/pride/archive/login).

**The iKAP algorithm**

The quantification result of the phosphoproteome was first preprocessed by averaging the quantification ratios for the same p-sites to remove any redundancy. Subsequently, the phosphopeptides with 7 residues flanking the p-site were submitted to iGPS for the prediction of ssKSRs and the construction of the mouse WKSPN (Fig. 3A, B). By default, we used the “Low threshold” and “Experiment/STRING PPI” filter. Species of “Mouse” was selected. In the network, the edges represent the ssKSRs, with assigned quantification ratios.

Based on the hypothesis that more important kinases preferentially induce more significant changes in the phosphorylation network, we first retrieved single kinase networks individually, and then separated a single kinase network into 2 subnetworks, including upregulated network and downregulated network, based on p-site ratios in the single kinase network (Fig. 3C).

Then, for any kinase $i$, the upregulated kinase activity $KA_{up}(i)$ could be inferred by summing up all of its upregulated phosphorylation sites in substrates $KS_{ij}$ in the upregulated network, whereas the downregulated kinase activity $KA_{down}(i)$ could be inferred by summing up all of its downregulated phosphorylation sites $KS_{ij}$ in the downregulated network. And total upregulated kinase activity $KA_{up}$ and total downregulated activity $KA_{down}$ can be calculated as below:

$$KA_{up}(i) = \sum_{j=1}^{n} int(KS_{ij})$$

$$KA_{down}(i) = \sum_{j=1}^{n} int(1/KS_{ij})$$

$$KA_{up} = \sum_{i=1}^{k} KA_{up}(i)$$

$$KA_{down} = \sum_{i=1}^{k} KA_{down}(i)$$

Yate’s chi-square test was used to compare the upregulated and downregulated kinases of an individual kinase with the following Chi-square $2 \times 2$ contingency table (Fig. 3D):

<table>
<thead>
<tr>
<th>Kinase $i$</th>
<th>Upregulated</th>
<th>Downregulated</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>$a = KA_{up}(i)$</td>
<td>$b = KA_{down}(i)$</td>
<td>$c = KA_{up} - KA_{up}(i)$</td>
<td>$d = KA_{down} - KA_{down}(i)$</td>
</tr>
<tr>
<td>$N_a = a + c$</td>
<td>$N_b = b + d$</td>
<td>$N = a + b + c + d$</td>
<td></td>
</tr>
</tbody>
</table>

The enrichment ratio ($E$-ratio) of kinase $i$ of the upregulated kinase activity against the downregulated kinase activity was calculated as below:

$$E = \frac{N_a}{N_b}$$

$E$-ratio > 1 means the kinase $i$ was preferentially to be upregulated, and vice versa. The $x^2$ was calculated as below:

$$x^2 = \frac{N(\max(0, | ad - bc | - N/2))^2}{N/N_1N_2N_3N_4}$$

Then the $p$-value (< 0.05) was calculated by the function of CHIDIST($x^2$, degree_freedom) in Excel. The degree_freedom is equal to 1 for the $2 \times 2$ table.
